

Elastáza 1 ve stolici

Stanovení elastázy-1 (EL-1) ve stolici

Lidskou pankreatickou elastázu 1 produkují acinární buňky pankreatu. Enzym je součástí **pankreatické šťávy**, která je produkována do duodena. Během střevní pasáže není degradována proteinová sekvence enzymu, která je zvolena pro immunochemickou detekci. Stanovení elastázy je proto více diagnosticky přínosná, než chromogenní metody stanovení chymotrypsinu ve stolici, význam nemá ani stanovení lipázy ve stolici. Aktivita lidské pankreatické elastázy 1 ve vzorcích stolice odráží **míru exokrinní pankreatické funkce**. Nejnovější aplikace doporučují stanovení pankreatické elastázy-1 v duodenální šťávě při stimulovaném **funkčním testu**. Klinický význam má stanovení elastázy-1 ve stolici v **diferenciální diagnostice**:

- malabsorpčního syndromu,
- jako screeningový test onemocnění pankreatu,
- dlouhodobé sledování nemocných s chronickou pankreatitidou.

Laboratorní metoda

Laboratorní metoda je založena na **imunologickém průkazu ELISA** metodou s monoklonální (nebo polyklonální) protilátkou k lidské, pankreatické elastáze. Vzorek stolice je v laboratoři homogenizován v extrakčním nárazníkovém roztoku a po ředění 1:500 dále zpracován běžným ELISA postupem na mikrotitrační destičce s detekcí pomocí POD-streptavidin. Souprava obsahuje 5 kalibračních standardů v rozmezí 0.3–10.0 ng/ml.

Referenční hodnoty

Referenční hodnoty jsou **200–500 µg/g stolice**, hraniční pásmo je 100–200 µg/g, závažná pankreatická insuficience je stanovena při hodnotách < 100 µg/g stolice. Imunochemické stanovení elastázy-1 není ovlivněno pasáží tlustým stěvem, substituční terapií ani jinými faktory, které ovlivňují enzymové stanovení chymotrypsinu ve stolici. Specifita metody je 93 %, senzitivita dosahuje pro těžkou pankreatickou insuficienci hodnoty 100 %, pro střední a lehké formy 87%. Tento test je běžně používán v pediatrii k průkazu cystické fibrózy se specifitou i senzitivitou téměř 100%. Falešná snížená hodnota může být způsobena zředěním (obsahem vody) při průjmu.
